

Why is the optical module 3.3V

Overview

Because the chip can handle only 3.3V. With things becoming more reliant on battery power, or power efficiency in general, lowering the voltage is a good way to save on power. 3.3V Controller Area Network (CAN) transceivers offer advantages and flexibility with respect to 5V CAN transceivers while being compatible and interoperable with each other. Power consumption is lower with 3.3V. There is potential for power supply. As an essential component of optical fiber communication, optical modules are optoelectronic devices that facilitate the conversion between optical and electrical signals during the transmission process. An optical module works at the physical layer of the OSI model and is one of the core components in the fiber communication. Every fiber optic transceiver is defined by a detailed set of specifications.

There have been multiple variants of the electrical interface of optical modules that have been used over the years. The earliest forms of optical modules had an analog NRZ electrical interface. In the transmit direction, the optical module would directly drive the laser or LED with the analog signal coming from the front system card. In the receive direction, the module would directly drive the receive electrical interface with the o
